Parent material determines the minerals that make up soil. Climate affects the rate of weathering. For example, a climate that is warm and wet speeds chemical weathering. Some biota that live in soil include decomposers that add organic matter to soil. Topography is a factor—steep slopes can slow soil formation, while flat areas can speed it up.

The types of weathering that take place within a region have a major influence on soil composition and texture. For example, in a warm climate where chemical weathering dominates, soils tend to be richer in clay. Soil scientists describe soil texture in terms of the relative proportions of sand, silt, and clay (Figure 8.21).
